

∇ giza: A Recipe for AI Languages

Arash Abadpour - arash@abadpour.com

November 12, 2023

Abstract

In this paper, we discuss the Mathematics of building Machine Vision AI systems in Linux. We review the general challenge of translating the description of an AI operation in human language into a human-readable, machine-executable script. We select multiple Machine Vision AI challenges that we first describe in human language. Then, in each case, we build the language to convert the description in human language into one or more scripts we execute on machines. We use AWS SageMaker ¹ for development and training and AWS Batch ² for inference and discuss API calls. The main contribution of this paper is a mathematical framework for building an AI language for a practical use-case in Machine Vision. We hope that researchers in other fields of AI use and extend this framework in their disciplines. We present a reference implementation ³ of this framework and multiple use-cases ⁴ - *revision-1.56.1*

Background and Context

Almost five years ago, on Thursday, November 8, 2018, I acquired a Raspberry Pi ⁵ on Amazon. Since then, my personal and professional lives have focused on Linux. Professionally, I do AI and, more recently, geospatial AI. In my personal life, I mix AI, cloud, and mathematics into minimal forms that seek survival ⁶. Over the years, I have built a set of mechanisms for building AI systems that I will document in this paper. Therefore, this is an attempt to produce formal mathematical definitions for the AI mechanisms that I will collectively refer to as *giza*. I seek to understand these mechanisms through this effort better to use them more optimally and along new dimensions.

This paper discusses concepts at the intersection of mathematics, software science, and computer science, and lacks scientific rigour in many places. I intend to push the practical development of this theory to fruition and hope to receive guidance along the way from experts in the field and solidify the theoretical foundations.

1 Problem Definition

challenges and solutions:

1. layers of computation.
2. wip.

2 Examples

2.1 OpenAI code generation

Experiments w/ the OpenAI API ⁷. wip

2.2 Vancouver-Watching (vanwatch)

`vanwatch` is a callable that,

1. terraforms the machine and the shell [5.2.1](#).
2. discovers the cameras in an area [2.2.1](#).
3. ingests images from the cameras discovered in an area [2.2.2](#).
4. detects the objects in the images ingested from an area and produces summary statistics [2.2.3](#).

2.2.1 vanwatch discover

Cameras are represented in different formats in different areas. `vanwatch discover area=<area>` discovers the cameras in `<area>` and stores them in `<area>.geojson` in the object `<object-name>` [3.4](#) tagged [5.2.8](#) for use for ingest [2.2.2](#).

```
vanwatch discover \  
  [area=<area>,~upload] \  
  [-|<object-name>] \  
  [<args>]
```

2.2.2 vanwatch ingest

`vanwatch ingest area=<area>,count=<count> <object-name>` finds the latest set of cameras discovered [2.2.1](#) in `<area>` through tag search [5.2.8](#) and ingests `count` images into `<object-name>` and then runs `vanwatch process` [2.2.3](#) unless `~process`.

```
vanwatch ingest \  
  [area=<area>,count=<-1>,dryrun,model=<model-id>,~process,~upload] \  
  [-|<object-name>] \  
  <args>
```

2.2.3 vanwatch process

`vanwatch process - <object-name>` runs object detection ⁸ on the images ingested into `<object-name>` and updates `<area>.geojson`. `vanwatch process` reuses the inference already present in the object and completes the missing pieces.

```
vanwatch process \  
  [~download,model=<model-id>,~upload] \  
  [.|<object-name>] \  
  [<args>]
```

3 Concepts

3.1 Machines and Shells

A *machine* is a state machine that is connected to many other machines and shares some of its state with them for read and write. A *shell* is a stateful access mechanism to a machine that an *operator* 3.2 uses to run *commands* 3.3. Running a command in a shell can modify the state of the shell, the machine on which the shell is running, and potentially the states of all other machines.

Machines and shells may be restarted by an operator or by code. After a restart, machines and shells maintain some of their state.

Two examples of machines are a Raspberry Pi that runs Linux and is connected to AWS ⁹ and a docker container running in AWS Batch. GNU Bash ¹⁰ is an example of a shell.

3.2 Operators

The *operator* generates commands and runs them on different shells on different machines. The operator attempts to maximize an objective function that depends on the state of multiple machines.

3.3 Commands

A *command* is any Bash command ¹¹ and can be represented in a Python string of characters ¹². Here is an example command,

```
vanwatch ingest \  
  vancouver \  
  dryrun \  
  . \  
  --count 12
```

The above command and the one below are *identical*.

```
vanwatch discover vancouver ~upload --validate 1
```

Two commands are identical if running them on two machines in identical states yields the same states. In theory, the state of any machine depends on the state of any other machine, and it is almost impossible to run two commands in identical states, including the time of execution. Therefore, when we refer to two identical commands, we either use a derivation-based proof of identity or consider a validation in a limited “relevant” subset of the state representation.

For any shell on any machine, at known states, there is a mapping between the set of all commands and $\{True, False\}$ that we address as “whether the command is found”. In Bash, for example, the following message is printed when a command “is not found”.

```
-bash: void: command not found
```

Note that writing to the standard streams *stdin* and *stdout* are examples of state changes in the shell and the machine.

Terraforming is the process of running commands that modify the state of the shell and the machine in ways that make additional commands found. Terraforming is also intended to modify the state change caused by a set of commands favourable to the interests of an operator. For convenience, we address a command “that is found” as a *valid* command and *invalid* otherwise. Terraforming may also ensure the states of the machine and the shell after a restart. Terraforming generally includes a modification of *bashrc*, *bash_profile*, *screenrc*, and *desktop* files.

Commands know the machine and the shell they are running in and adjust their operation accordingly. For example, a script that submits jobs when run inside a docker container may download the artifacts generated through previous runs when run on a user-facing machine, such as a Mac Book.

¹⁰<https://www.gnu.org/software/bash/>, *Bash*, *bash*.

¹¹<https://www.gnu.org/software/bash/manual/bash.html#Shell-Syntax>

¹²<https://docs.python.org/3/library/string.html>

3.3.1 Callables

A *callable* is a valid command with no space and control operators¹³. The list of callables depends on the machine's state and is generally extended through terraforming. Some of the well-known callables are *git*¹⁴, *docker*¹⁵, *pushd*¹⁶, *nano*¹⁷.

Theorem 1 For any callable $\langle callable \rangle$, and any string $\langle suffix \rangle$, “ $\langle callable \rangle \langle suffix \rangle$ ” is a valid command.

Theorem 2 For any valid command $\langle command \rangle$, and any string $\langle suffix \rangle$, “ $\langle command \rangle \langle suffix \rangle$ ” is a valid command.

3.3.2 Command Templates

Commands can be similar when considered as strings of characters. Here is a command that is similar to the above,

```
vanwatch ingest toronto upload . --count 3
```

A *command template* is a representation that yields similar commands, given the following rules. First, $\langle description \rangle$ can be replaced with any string of characters that can be described as “description”. See *objects* 3.4, *options* 3.3.3, and *arguments* 3.3.4, for the next rules. Here is a command template for the two above,

```
vanwatch ingest \  
  <area> \  
  [dryrun,~upload] \  
  [<object-name>] \  
  [--count <-1>]
```

3.3.3 Options

An *options* is a string representation of a dictionary, such as $\langle keyword \rangle = \langle value \rangle, \langle keyword \rangle, -\langle keyword \rangle$.

3.3.4 Arguments

Any list of arguments that is consumable by a Linux tool. An example is a series of $--\langle arg \rangle \langle value \rangle$.

3.4 Objects

Objects are accessible on every machine by their *name*, and an object may be *selected* 5.2.7. Objects may be uploaded 5.2.9 and downloaded 5.2.2, fully or partially, or listed 5.2.5. Objects have metadata 3.4.1.

Commands 3.3 consume and generate objects. If the object name is not provided or is given as “-”, then an object with a unique name is created and used. Otherwise, the object is either provided by name, as in $\langle object-name \rangle$, or by reference, as in one of “.”, “..” or “...” 5.2.7.

In its most basic form, an object is an S3 bucket¹⁸.

3.4.1 Object Metadata

metadata is information about Objects 3.4, such as their *tags* 5.2.8 and relations 5.2.6.

3.5 Computational Model

A group of operators create and modify a set of scripts 5.2.10 maintained in a code repository, such as *git* 5.2.3. The core 5.2 and the plugins 5.3 are also maintained in one or more repositories. Each operator can access a set of machines and create shells on them. Each operator can also access a set of repositories and clone them on the machines where they create shells and receive updates. The operator can modify any of the repositories that they have access to following a collective peer-reviewed *pull-request* ¹⁹ process.

The operators act asynchronously while communicating with each other. Multiple operators may simultaneously use the same machine, and the same operator may simultaneously use multiple machines. Only one operator uses a shell at one time.

Some machines are exogenous to this model, yet the operators can access their states in read or write mode. Cloud storage and compute resources are examples of these machines.

4 Mathematical Model

operations: pre and post-fixing, batch multi-dimensional, deep injection.

5 TL;DR

This section provides a set of practical guidelines for building a Machine Vision AI language based on a hybrid of Python ²⁰ and Bash.

5.1 Before you Start

5.2 Build the Core

The *core* is a callable that loads the plugins and terraforms the machine.

5.2.1 @conda

5.2.2 @download

```
@download object <object-name> [filename=<filename>,open]
```

5.2.3 @git

```
git pull
```

5.2.4 @help

When the command ends with `help` a help message should print.

5.2.5 @list

5.2.6 @relations

Two objects can be related in many ways.

```
@relations get <object-name-1> <object-name-2>
@relations get <object-name-1> <object-name-2> <relation>
@relations get <object-name-1>
@relations get <object-name-1> <relation>
```

```
@relations search <relation>
```

```
@relations set <object-name-1> <object-name-2> <relation>
```

5.2.7 @select and object references

```
@select object <object-name>
@select <type> <type-name>
```

When an object is selected, `'.'` represents $\langle \text{object-name}_i \rangle$. Similarly, `'..'`, `'...'`, and so on, as deep as needed, refer to the previously selected object and the one before that.

Commands default the objects they consume and modify to `'.'`, `'..'`, and so on. Because the commands in a script use the same objects, selecting the objects enables their names to be omitted in a script.

An object may have a 'type', for example, 'model' or 'dataset'. Commands that consume objects specify a 'type' for the argument. This enables the user to simultaneously select different types of objects and run commands on them. Here is an example from *hubble* ²¹, wherein the user selects an object and then a hubble dataset and an object in that dataset to download in the object.

```
abcli select; open .
hubble select dataset hst
hubble select object public/u4ge/u4ge0106r
hubble download ~dryrun
```

²⁰<https://www.python.org/>

²¹<https://github.com/kamangir/hubble>

5.2.8 @tag

An object can have many tags. A tag is a boolean or valued property of the object.

```
@tags get <object-name>
```

```
@tags get <object-name> <keyword>
```

```
@tags search <keyword=value,~that,this>
```

```
@tags set <object-name> <keyword=value,~that,this>
```

5.2.9 @upload

```
@upload object <object-name> [filename=<filename>]
```

5.2.10 Scripts

The script is a bash script ²².

5.2.11 @start

5.3 Establish a Plugin Mechanism

A plugin generally defines one or more callables.

²²https://en.wikipedia.org/wiki/Shell_script
